MonoMobility: Zero-Shot 3D Mobility Analysis from Monocular Videos

Supplementary Material

Summary

The supplementary material consists of the following two parts: (1) A detailed introduction to the dataset, including both the synthetically simulated scenarios and the real-world captured scenarios; see Section 1. (2) Additional visualization results, including qualitative comparison experimental results with state-of-the-arts methods [3, 5], as well as more qualitative experimental results of our method; see Section 2.

1. Details of Dataset

Our goal is to analyze motion parts and their motion attributes from monocular videos. For effective evaluation of our algorithm, we have constructed a Motion Parsing Dataset that primarily comprises virtual simulation and real-world scenarios. It includes various common articulated object categories such as drawers, wardrobes, laptops, staplers, and liftchairs, which cover three main types of articulated motion: translation, rotation, and rotation+translation. Some scenes contain multiple motion parts with different motion types, aimed at verifying the effectiveness of relevant algorithms in solving complex tasks. The statistical details of the dataset are presented in Tab.1.

Figure 1. Virtual simulation scenarios. Each row represents a sequence of video frames captured in a virtual scene.

1.1. Virtual Simulation Scenarios

For virtual simulation scenarios, we first collect 3D models from 3D Warehouse [2] and annotate the motion parts and motion attributes using Blender [1]. Subsequently, robots are introduced into the scenes to simulate the interaction operations of articulated object. Finally, the constructed dynamic scenes are rendered using Blender [1], capturing motion videos sequences. To quantitatively analyze the results of the motion parts and motion attributes parsing, we also captured 3D point clouds with annotations of motion parts and motion attributes. A total of 15 virtual motion simulation scenarios were built, some examples are shown in Fig.1.

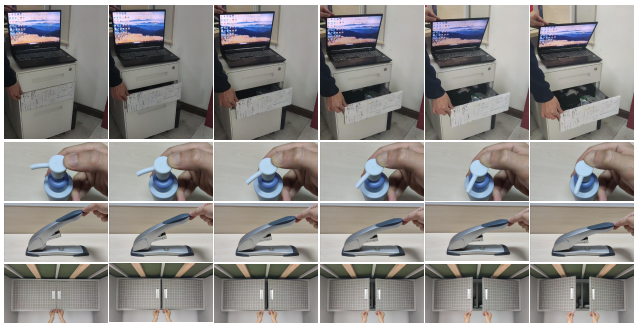

Figure 2. Real-world scenarios. Each row represents a sequence of video frames captured in a real-world scene.

1.2. Real-world scenarios

For real-world scenarios, we use the camera directly capture motion videos of articulated objects. The intrinsic parameters of camera are calibrated using COLMAP [4]. Unlike virtual simulation scenarios, we cannot obtain geometric and annotation information for real-world scenarios. Therefore, we only perform qualitative analysis on the real-world data. A total of 11 real-world scenarios were constructed, some examples are shown in Fig.2.

2. Additional Experimental Results

To further substantiate the superiority and effectiveness of our method, we conducted qualitative comparisons in motion parameter prediction with the state-of-the-arts algorithms (PARIS-scene, PARIS-obj [3], DGMarbles* [5], and ours(w/o optim)) on additional data, as shown in Fig. 3; as well as more qualitative analysis results of motion parts and motion attributes of our method from more video sequences, detailed in Fig. 4–17, where each figure includes the analysis results of two scenes. For each scene, the first row represents the input (video sequence) to the algorithm, while the second to fourth rows show the continuous motion visualization of motion parts based on motion attributes from different viewpoints.

Data Type	Number of Scenes	Number of Motion Parts	Distribution of Motion Types	Object Categories
Virtual	15	18	10×rotation	Fridge(3), Door(1), Cupboard(4), Faucet(1), Laptop(1)
			7×translation	Drawer(6), Flatdoor(1)
			1×rotation-translation	Liftchair(1)
Real-world	11	13	8×rotation	Cupboard(3), Laptop(3), Wrench(1), Stapler(1)
			4×translation	Drawer(4)
			1×rotation-translation	Pumpbottle(1)

Table 1. The statistical of the dataset. '10×rotation' indicates that the rotation motion type contains 10 motion parts, 'Fridge(3)' indicates that the articulated object category ''Fridge' contains 3 motion parts, and similar symbols apply accordingly.

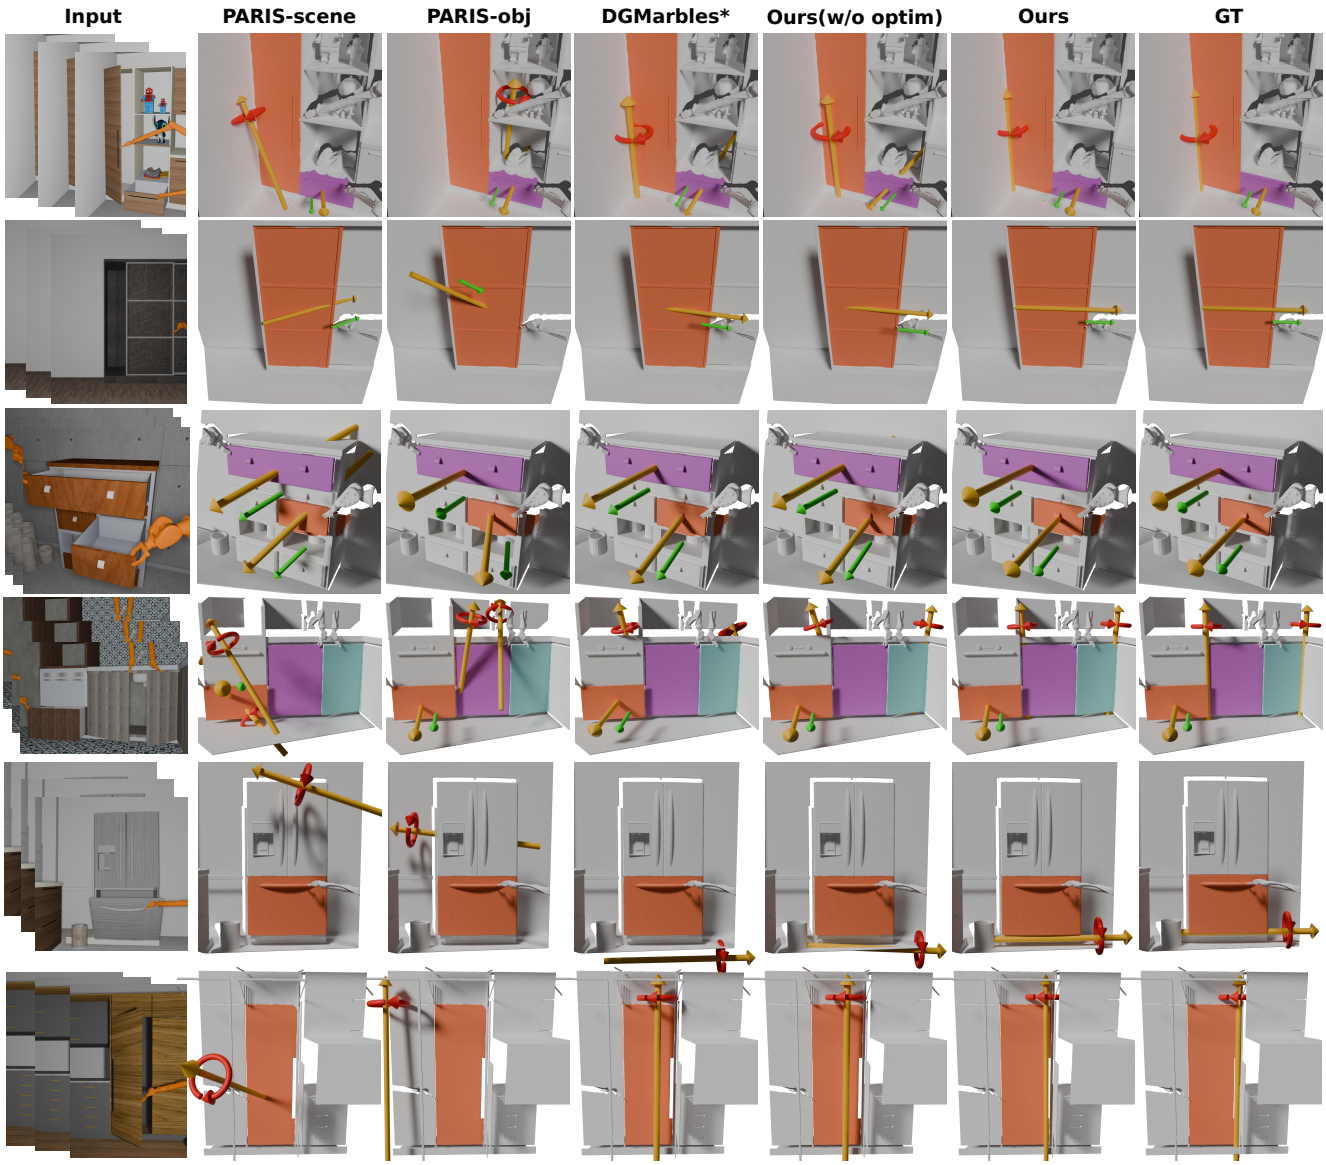

Figure 3. More qualitative comparison with state-of-the-arts methods (PARIS-scene, PARIS-obj, DGMarbles*) and Ours(w/o optim).

Real-world Data Results
